

Customer interacts → AI understands customer → AI responds → AI recommends/acts → backend intelligence supports employees/admin

So **Topic A** is primarily customer-facing, while **Topic B** works mainly in the background or employee/admin side of the same application.

My understanding of the overall structure

Topic	Nature	User
A. Customer-facing Chatbot / Voice Bot	Conversational interface	Customer
B. Interactive Assistants & Intelligence	Decision/workflow intelligence	Bank employee / system / admin

The same customer conversation can feed Topic B. That is what makes a **single application** especially sensible.

A1. Customer Service & Query Handling

This is the **basic conversational banking assistant**.

The customer should be able to ask questions naturally through chat, and potentially voice later.

Examples:

“What is the minimum balance requirement?”

“How can I block my debit card?”

“What documents are required for a home loan?”

“Mujhe cheque book order karni hai.”

The AI should understand the question, answer from approved bank knowledge, support multiple languages, maintain conversational context, and identify when the customer needs an actual service rather than information.

Pre-empt Service Request is important here

Customer:

“My debit card has not been working since yesterday.”

Instead of just giving instructions:

AI: “I can help you raise a service request for this issue. Would you like to proceed?”

So my understanding is:

Query Resolution + Multilingual Conversation + Contextual Q&A + Proactive Service Request Suggestion

A2. Customer Sentiment Analyzer Chatbot

This goes beyond answering the customer's question.

The AI should continuously understand **how the customer feels and how the interaction is progressing**.

For example:

Customer:

“This is the third time I am contacting the bank and nobody has resolved my issue.”

The system may identify:

Sentiment: Highly Negative

Emotion: Frustrated

Intent: Complaint

Interaction Quality: Poor / At Risk

Resolution status: Unresolved

After the conversation it can generate:

- Conversation summary
- Customer issue
- Sentiment
- Reason for dissatisfaction
- Resolution status
- Customer expectation
- Suggested next action

It could also capture **CSAT/NPS**:

“How satisfied are you with this interaction?”

Personalization based on sentiment

This part is particularly interesting.

If someone is frustrated, don't immediately push a sales offer.

If someone has successfully resolved a query and has positive sentiment, the system may determine that an engagement opportunity exists.

So my understanding:

Understand the interaction → measure CX → summarize → derive sentiment insights → influence subsequent engagement.

A3. Lead Engagement / Qualification Chatbot

This is primarily a **sales-conversion capability**.

A customer visits the bank website and asks:

“I am thinking about buying a house.”

Instead of just displaying home-loan information, the AI starts a conversation.

It could ask:

Required amount → Monthly income → Employment type → Existing EMI → Location → Timeline

Based on this interaction, the system determines:

Product Interest: Home Loan

Customer Intent: High

Lead Score: 86/100

Lead Status: Hot

Next action: RM callback

Drop-off management

This is another important portion of the use case.

Imagine the customer starts:

Home Loan → ₹40 lakh → Salaried → enters income → exits

The application retains the journey stage.

It could identify:

Journey abandoned at eligibility stage

and create a follow-up opportunity.

For the PoC we don't necessarily need automated calling. We can demonstrate:

Drop-off detected → lead identified → suggested follow-up/nudge

So:

Engage → understand intent → collect lead information → qualify → score → follow up.

A4. Personalized Conversational Financial Coach

This one should be distinctly different from product selling.

The customer should be able to discuss a **financial objective or financial situation**.

Example:

“I earn ₹70,000 per month. My expenses are around ₹45,000. I want to save ₹5 lakh for a car.”

The conversational coach might help organize:

Income: ₹70K

Expenses: ₹45K

Surplus: ₹25K

Goal: ₹5 lakh

Goal timeline: 24 months

And provide general guidance around:

- budgeting
- savings goals
- emergency fund
- spending categorization
- financial discipline
- goal tracking

Potentially, relevant bank products can later be surfaced, but **the primary objective should remain guidance**, otherwise it becomes the product recommendation use case.

So:

Understand financial situation → understand goal → give personalized conversational guidance.

B1. Guided Sales, Engagement & Product Recommendation Assistant

This is where I see a very important distinction from A3.

A3 Lead Qualification

“How interested/qualified is this customer?”

B1 Product Recommendation

“What should the bank recommend to this particular customer?”

For example, customer information indicates:

- Salary account customer
- ₹5 lakh average balance
- No term deposit
- Regular monthly surplus

The background engine could identify:

Opportunity: Term Deposit

The employee/RM side could show:

Recommended Next Best Product: Fixed Deposit

Reason: Sustained surplus balance

Suggested Engagement: Explain FD tenure options

Personalized content

It could also generate an appropriate communication:

“You currently maintain surplus funds in your account. You may explore our term deposit options...”

The employee can review it before sending.

Lifecycle-triggered offers

This becomes even more powerful.

Examples:

Salary credited for 6 months → suitable credit offer

Home loan nearing completion → home improvement product opportunity

FD maturity approaching → renewal engagement

So my understanding:

Customer/profile/context → AI identifies opportunity → recommends product → generates personalized engagement.

B2. Customer Retention & Win-back Assistant

This is different from ordinary sales.

Here, the question is:

“Which customer may leave/disengage, and what can the bank do about it?”

Potential signals:

- repeated complaints
- poor sentiment
- declining interactions
- low usage
- product closure request
- negative CSAT
- abandoned relationship
- service failures

Example:

Customer:

“I am fed up. I'm going to close my account.”

Customer-facing sentiment engine captures that.

The background retention engine then generates:

Attrition Risk: High

Reason: Repeated unresolved service complaints

Recommended action: Priority relationship-manager intervention

It could also create personalized **win-back content**.

For an already disengaged customer:

Previous relationship → reason for disengagement → suitable win-back campaign/message

So:

Identify churn/attrition signal → understand reason → recommend retention action → generate personalized win-back engagement.

B3. Service Sentiment & Routing Intelligence

This should be kept distinct from A2 despite using the same sentiment data.

A2 asks:

“What does this customer feel?”

B3 asks:

“What should the servicing system do because of that?”

Example:

Customer says:

“My account has been wrongly debited and nobody has helped me for five days.”

AI detects:

Sentiment: Highly Negative

Issue: Account debit dispute

Urgency: High

Repeat Contact: Yes

Instead of putting the request into a normal queue:

Route → Priority servicing queue

or:

Escalate → Supervisor/RM

This is what I interpret from:

“Sentiment Analysis on service interactions that feeds servicing modules.”

The intelligence shouldn't end at displaying a sentiment score.

It should **feed another workflow/module and influence servicing priority or routing.**

So:

Interaction → sentiment/urgency intelligence → servicing module → appropriate queue/escalation.

How all seven fit into ONE application

This is where I think the concept can become very strong.

Imagine the application has two sides:

Customer Side

Union Engage AI

Customer gets one interface containing:

Chat / Voice Assistant

Behind that single conversation, AI can invoke:

Query Assistance

Sentiment Analysis

Lead Qualification

Financial Coach

Bank / Employee / Admin Side

The same application has an authenticated employee/admin dashboard.

It receives intelligence from customer interactions and provides:

Guided Sales & Product Recommendations

Retention / Win-back Opportunities

Sentiment-based Service Routing

So conceptually:

CUSTOMER

↓

Chat / Voice

↓

Intent + Context + Sentiment Intelligence

↓

Query Resolution | Lead Qualification | Financial Coach

↓

Customer Interaction Data

↓

Product Recommendation | Retention Intelligence | Service Routing

↓

Employee / RM / Service Team

That is a very coherent **single-application story**.

The strongest part of the design is that we do **not need to manufacture seven independent modules**. One customer conversation can generate signals that power several EASE use cases simultaneously.
